SOME UNUSUAL CIPHERS: PROTEX AND KEELOQ

G J Kühn
Ciphertec cc
gjkuhn@global.co.za

Contents

- **Protex**: First electronic crypto device in designed in South Africa
- **Keeloq**: A simple but effective secure remote entry device

PROTEX CIPHER

A rotor-inspired electronic cipher device

Rotor Cryptographic Machines

- The Protex cipher was based on rotor machine prototypes, such as
 - Enigma
 - Tsec-KL/7
 - Typex

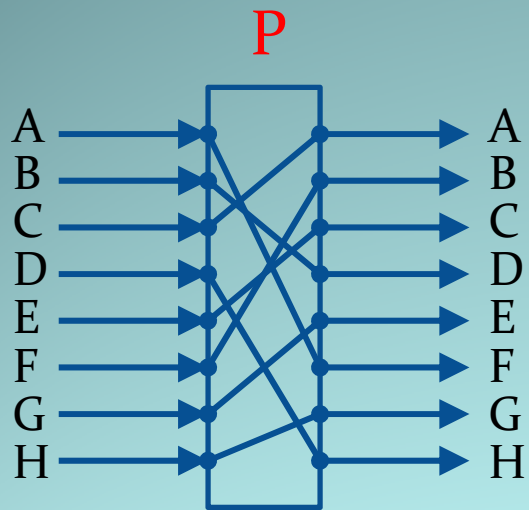

The Enigma machine was used commercially from the early 1920's, and was adopted by the militaries and governments of various countries.

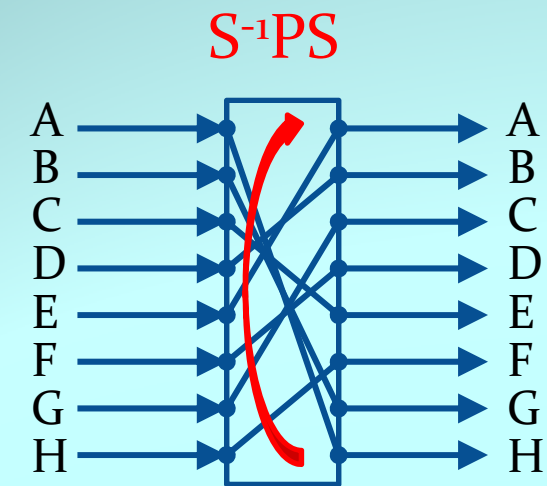

[Wikipedia]

Rotor Disk

P = Permutation embedded in rotor

S = Single step cyclic permutation

TSEC/KL-7 adopted by the US National Security Agency

Typex

- British cipher machine in use from 1937
- Based on the Enigma

Concatenation of r Rotors

$$P = S^{-i_1} P_1 S^{i_1} \cdot S^{-i_2} P_2 S^{i_2} \cdot \dots \cdot S^{-i_r} P_r S^{i_r}$$

where

P_1, P_2, \dots, P_r are the rotor permutations

S is a 1-step rotation operation

$\sigma = (i_1, i_2, \dots, i_r)$ is the state of the machine

Reflection Disk

$$\begin{aligned}
 Q &= S^{-i_1} P_1 S^{i_1} \cdot S^{-i_2} P_2 S^{i_2} \cdot P_r \cdot S^{i_2} P_2^{-1} S^{-i_2} \cdot S^{i_1} P_1^{-1} S^{-i_1} \\
 &= X^{-1} P_r X
 \end{aligned}$$

Q and P_r are conjugate permutations with the same *cycle structure*

Rotor Cycle Structure Properties

- Advantage:
 - Encryption/ decryption operations are identical
- Weakness:
 - A given letter is never encrypted into itself
 - This is due to the turn-around permutation being self-inverse with no fixed points – all cycles are of order **2**
 - This represents a Shannon redundancy of **0.057** bits/letter

Re-entry

- The technique matches the alphabet size to the number of contacts on the rotor

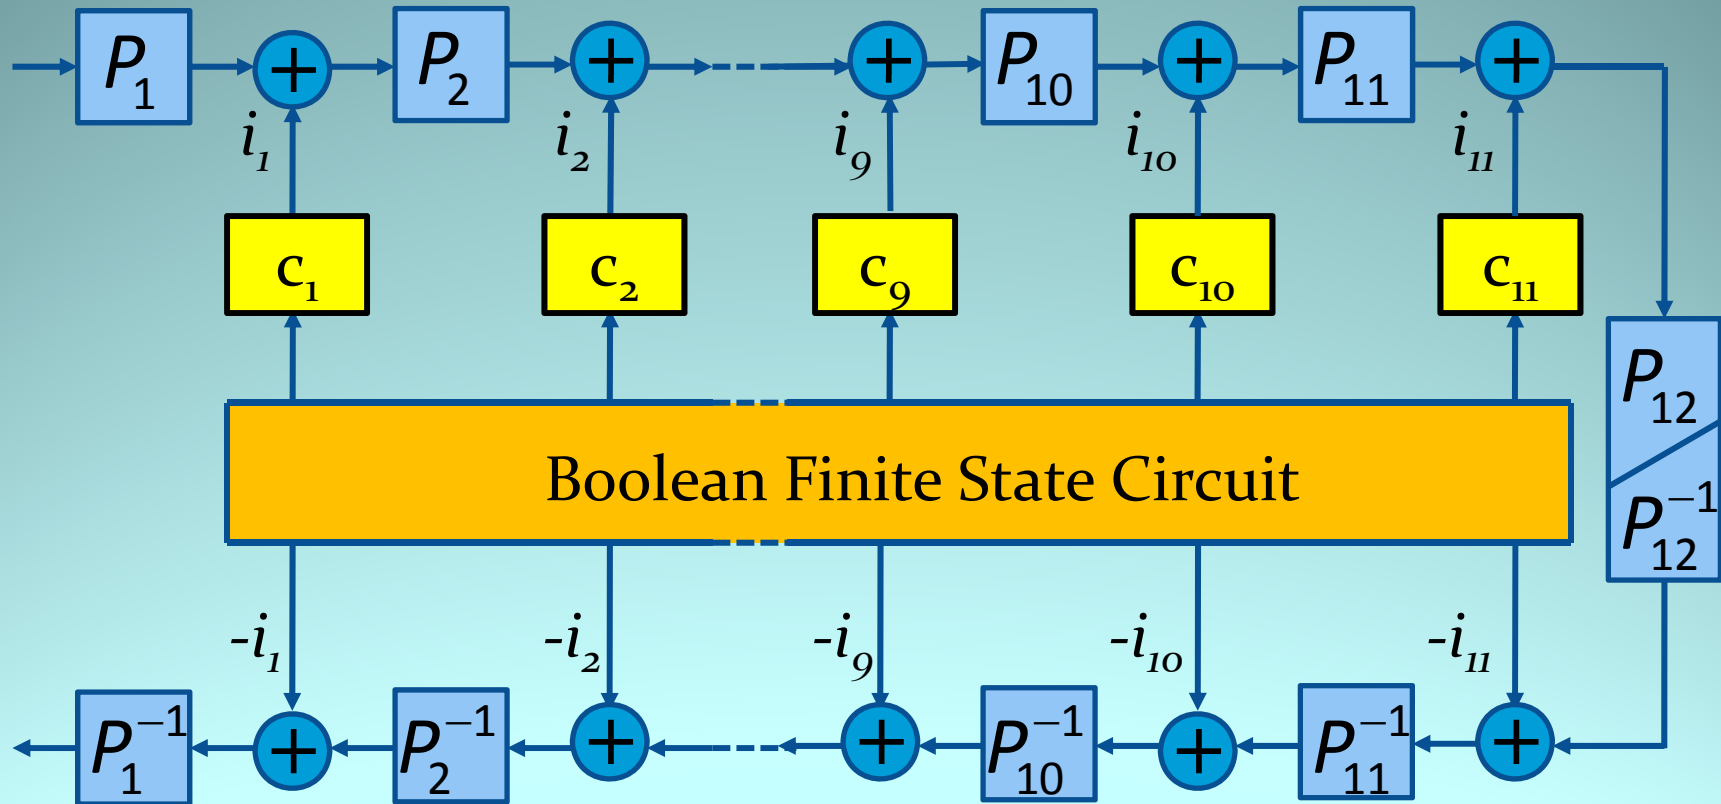

KL-7: 26 : 36 : 26
Protex: 26 : 32 : 26

$B \rightarrow D \rightarrow 1 \rightarrow E \rightarrow C$

Protex Design

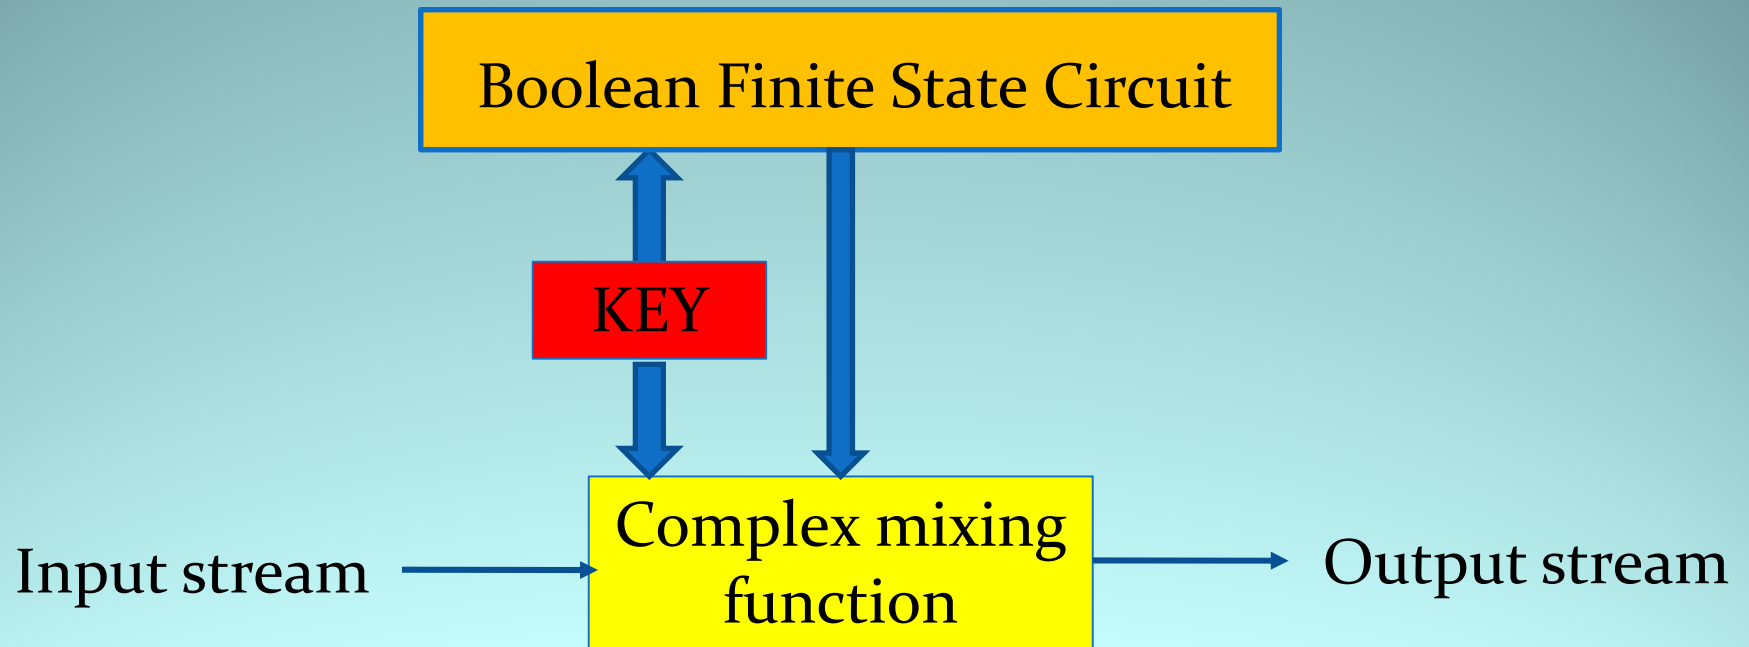

- 5-bit alphabet
- 12 random permutations on 32 characters
 - One permutation is used as a reflector
 - The permutations are chosen such that $P \cdot S \neq S \cdot P$
(*Shannon product cipher condition*)

Protex Encryption/Decryption

Decryption uses P_{12}^{-1} as turn-around permutation

Rotor Machine Categorisation

Stream cipher with a dynamic key-dependent mixing function

Key Size

- BFSC initial state : $11 \times 5 = 55$ bits
- Counters initial states : $11 \times 5 = 55$ bits
- Ordering of 12 permutations: $12! \approx 28.8$ bits

- **Total key size : 138.8 bits**

Re-Entry

- Re-entry on six 5-bit teleprinter control characters

No. of re-entries	Probability
0	0.812500
1	0.157258
2	0.026210
3	0.003615
4	0.000387
5	0.000029
6	0.000001

Average = 0.22

Implementation

Ferrite core
memory storing 12
permutations and
their inverses

Permutations were
optimised to
reduce the number
of conductors
threaded through
each ferrite core

S-Box

Laboratory model S-Box showing 5 planes corresponding to the 5-bit words

Patch Panel

Patch panel to select a rearrangement of the $12!$ permutations

Attacks on Protex

- Cryptanalysis depends critically on the properties of the BFSC
 - Advance of the counters are irregular
- Side-channel attacks:
 - Timing attacks
 - Re-entry
 - Propagation of carry bit
 - Power analysis
 - Power surges due to switching of magnetic ferrite cores

Benefit of Hindsight

- The reflector structure of rotor machines offers no cryptographic advantage
 - Input-output permutations conjugate to a fixed permutation decreases entropy
- Re-entry is a serious weakness, making the cipher vulnerable to a timing attack

KEELOQ CIPHER

The travails of a 32-bit block cipher

KEELOQ

- Designed at Nanoteq in the 1980's
- Purpose: To provide increased security for remote keyless entry systems
 - Applications: car door, garage door openers, etc.
- Constraints
 - 32-bit radio transmission
 - low power
 - low component count

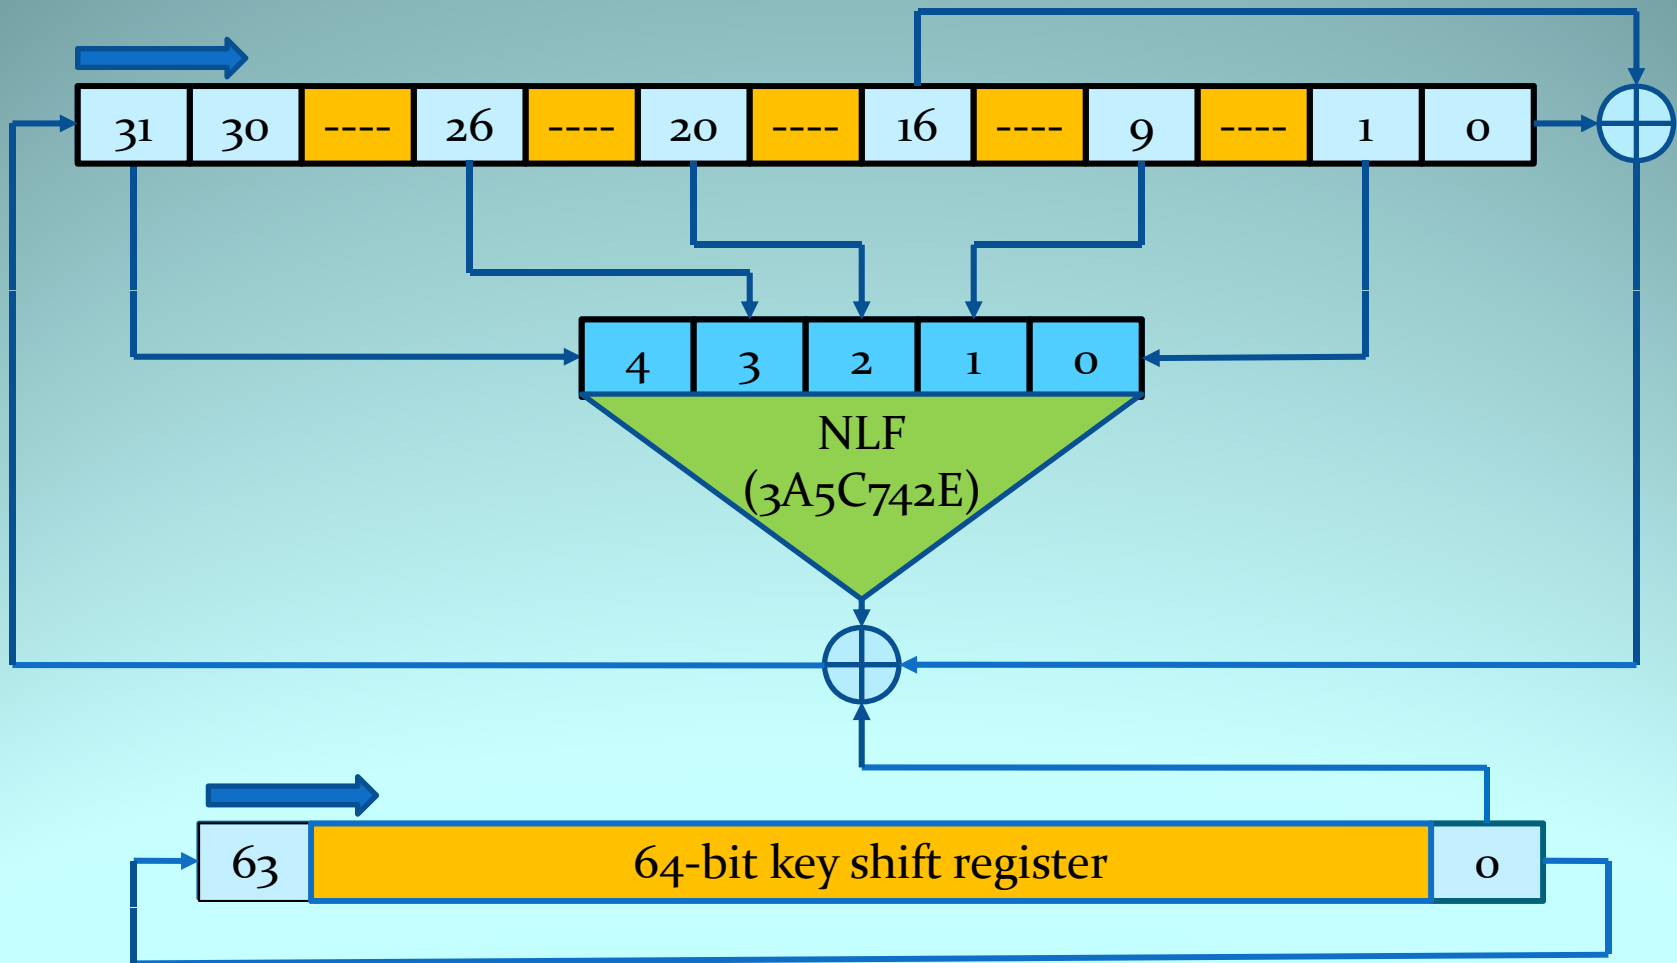

Protocol

- A block cipher to encrypt the state of a counter
- Key length: Initially 32 bits, but later increased to 64 bits
- Block length limited to 32 bits due to transmitter constraints

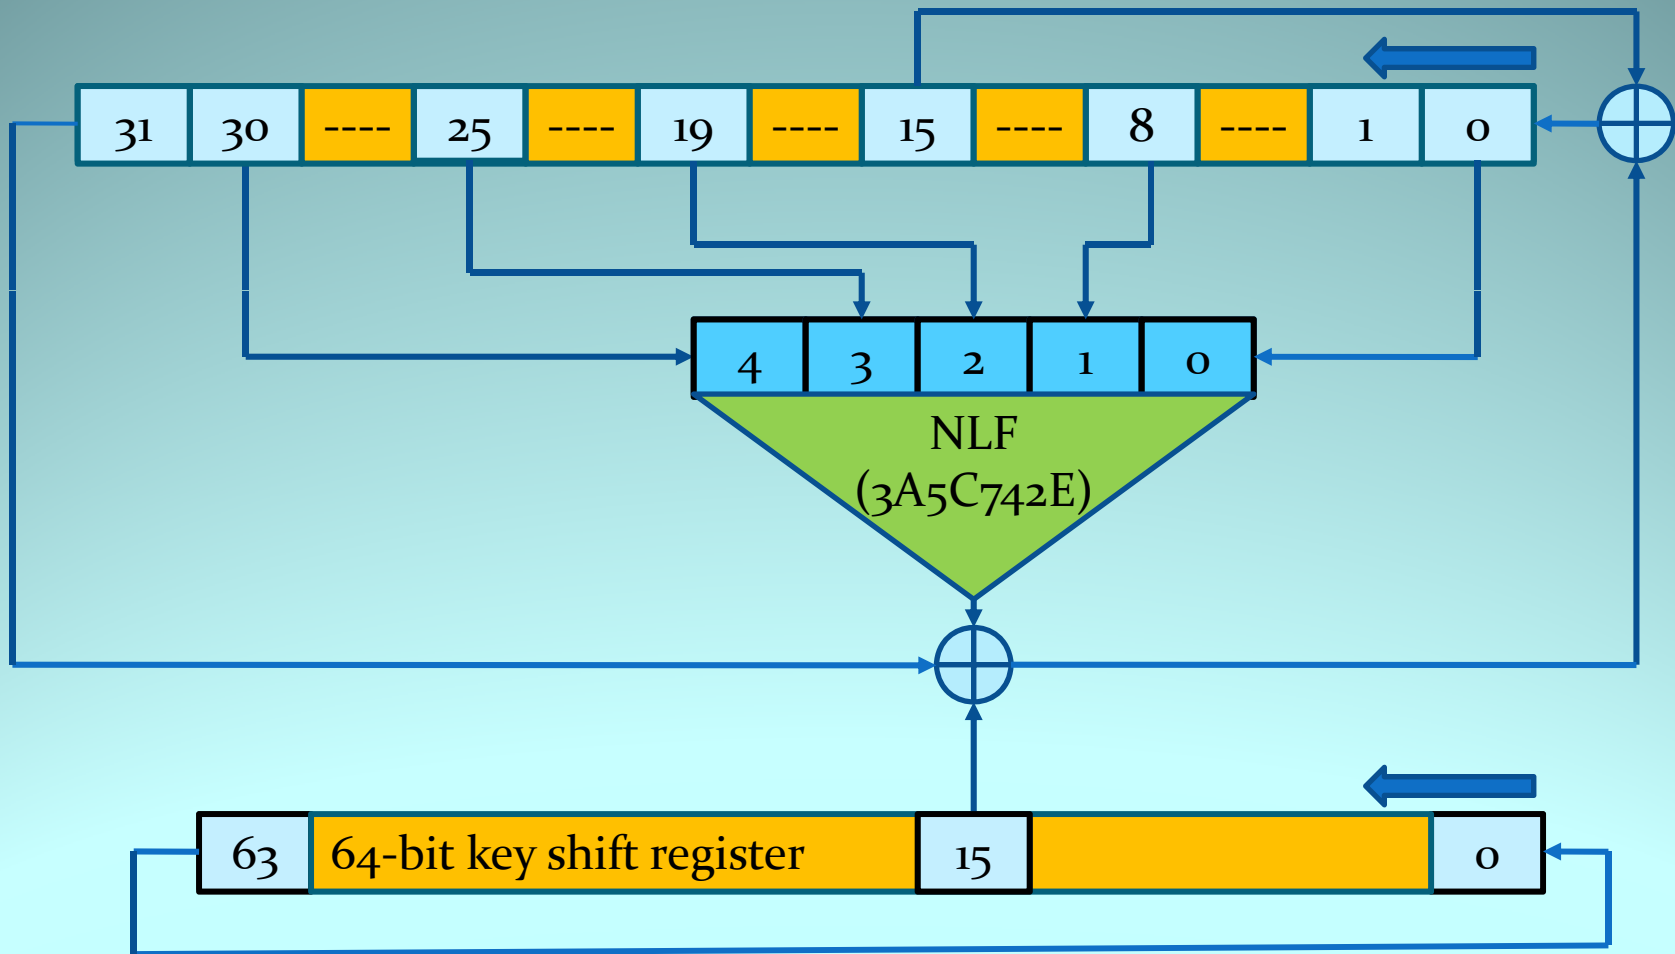

Design

- No *nxn* S-boxes, as these would be too expensive in component count
- Eventually it was decided to insert a single *5x1* S-box
- An *elementary key schedule* to save components
 - Circulating shift register

Keeloq Encryption

Keeloq Decryption

Number of Steps (Rounds)

- Number of shift register steps: 528
- This was decided on as follows
 - Good SAC properties from plaintext to ciphertext
 - Each key bit should be active at least 8 times
- The 528 steps comprises $8\frac{1}{4}$ cycles of the key register
- The $\frac{1}{4}$ cycle was introduced as a “nuisance” impediment to cryptanalysis

Tap Points on the Shift Register

- Latency: 1 clock period
 - Minimised to enhance diffusion of bit changes in encryption/decryption

The Non-Linear Function (NLF)

- Properties
 - 5-bit Boolean function
 - 0-1 balanced
 - Algebraic degree : 3
 - Minimum distance to affine set : 8
 - Correlation immunity : 1
 - Function resiliency : 1

Attacks on Keeloq

Attack	Data	Time	Mem	Reference
Exhaustive search	2 KP	2^{63}	Small	
Time-memory trade-off	2 CP	$2^{42.7}$	100 TB	Hellman
Slide/algebraic	2^{16} KP	$2^{51.4}$?	[Co, Ba, Wa]
Slide/guess and determine	2^{32} KP	2^{37}	16 GB	Bogdanov
Slide/cycle structure	2^{32} KP	$2^{39.4}$	16.5 GB	[Co, Ba]
Slide/fixed points	2^{32} KP	2^{27}	>16 GB	[Co, Ba, Wa]
Slide/meet-in-the-middle	2^{16} KP	2^{45}	≈ 2 MB	[In, Ke, ...]

Exhaustive Search

Exhaustive Search

- Computational Complexity = 2^{63}
- Time: 2 weeks using FPGA circuits

Most significant half (MSH)	Criterion	Number of ciphertexts
MAC = $f(\text{counter})$	MSH* Satisfies MAC	2
Fixed ID (known)	MSH Equals ID	2
Fixed ID (unknown)	MSH differential	3
Random bits	16-bit counter mode	≤ 64

* MSH = most significant half of counter

Deduced Plaintext for Exhaustive Search Attack

- Guess the state of the binary counter
 - The date of purchase of the car and the usage pattern of the driver might give a clue
 - At a usage pattern of 10 transmissions per day, the wrap-around period is approximately 18 years
- If the top bits are determined by the serial number of the transmitter, this provides the attacker with substantial information

Cryptologists Involved

- Bogdanov: **Guess-and-determine, slide, and distinguishing attacks**
- Courtois, Bard and Wagner: **Slide-algebraic attack**
- Indestege, Keller, Dunkelman, Biham and Preneel: **Slide- and meet-in-the-middle attacks**
- Eisenbarth, M & T Kasper, Moradi, Paar, Salmasizadeh, Shalmani: **Power analysis**

Algebraic Attack

Keeloq Algebraic Equations

- $NLF(x_4, x_3, x_2, x_1, x_0) = x_0 \oplus x_1 \oplus x_0 x_1 \oplus x_0 x_3 \oplus x_0 x_4 \oplus x_1 x_2 \oplus x_2 x_3 \oplus x_2 x_4 \oplus x_0 x_1 x_4 \oplus x_0 x_2 x_4 \oplus x_1 x_3 x_4 \oplus x_2 x_3 x_4$
- Add 2 variables $\alpha = x_3 x_4$ and $\beta = x_0 x_4$
- Assume F bits of the key are known, then for r rounds of the cipher, there are $3r + 64 + F$ multivariate quadratic equations in $3r + 96$ variables of which $64 + F$ are known
- The total number of distinct monomials is approximately $12r$

Complexity of Algebraic Attack

- Faster than exhaustive search on reduced Keeloq:
 - With $r = 128$, 2 known plaintexts, 30 bits guessed, the remaining 34 bits are recovered in 150 s by the program MiniSat 2.0
 - With $r = 160$ rounds, 2 plaintexts in counter mode, 30 bits guessed, the remaining 34 bits are recovered in 233 s by the program MiniSat 2.0

Linear Slide Attacks

Linear Slide Attacks

- Data requirement: 2^{32} known plaintexts (Full code book)
- Basis of attack:
 - Self-similar key schedule (supports slide attack)
 - Efficient linear approximation to the NLF
 - Existence of linear relations within the algorithm

Slide Attack

A pair $(P, C), (P^*, C^*)$ is called a *slid pair* if
 $F(P) = P^*$ and $F(C) = C^*$

Complexity of the Slide Attack

- Assume that P and P^* is a slid pair, then so is C and C^*
- Use this information to solve for K
- Verify the solution by checking additional plaintext-ciphertext pairs

Complexity

1. The attacker is searching for collisions, which, due to the birthday paradox, have a high probability after $2^{n/2}$ pairs have been searched
2. Solving for K should be $\ll 2^K$

Linear Approximation to NLF

$$\text{NLF}(x_4, x_3, x_2, x_1, x_0) = x_0 \oplus x_1 \oplus x_0 x_1 \oplus x_0 x_3 \oplus x_0 x_4 \oplus x_1 x_2 \oplus x_2 x_3 \oplus x_2 x_4 \oplus x_0 x_1 x_4 \oplus x_0 x_2 x_4 \oplus x_1 x_3 x_4 \oplus x_2 x_3 x_4$$

- The best linear approximation, used in the slide-determine attack, is $x_0 \oplus x_1$.

$$\Pr(\text{NLF}(x_4, x_3, x_2, x_1, x_0) = 0 \mid x_0 \oplus x_1 = 0) = 5/8$$

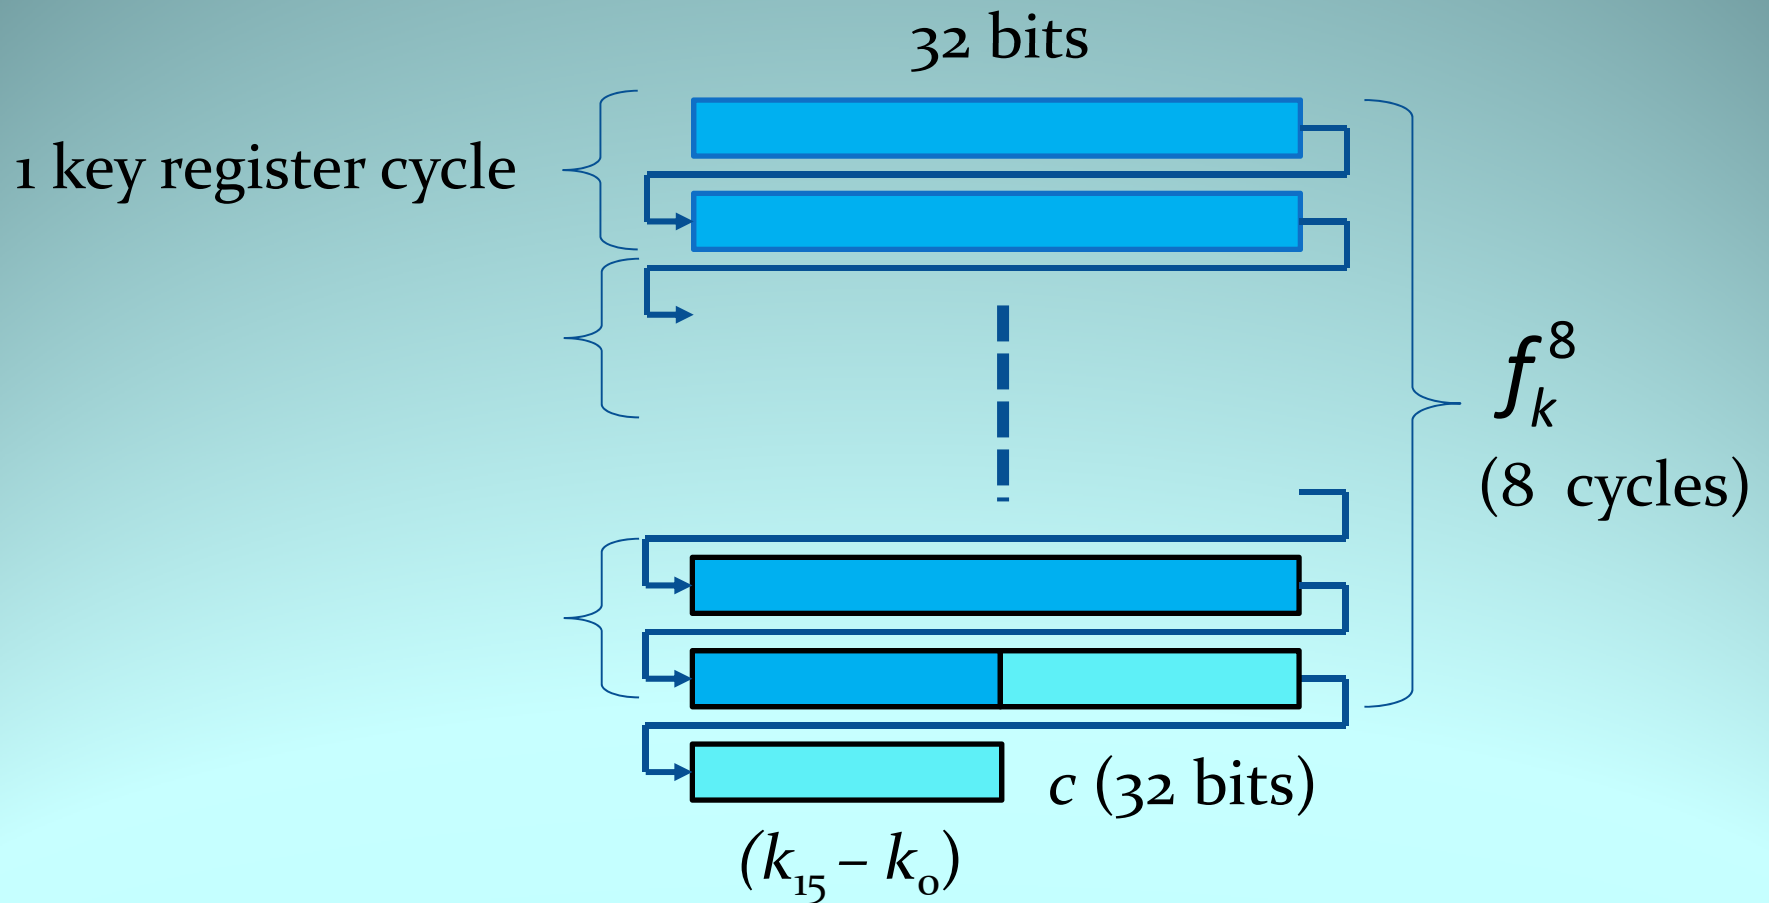

$$\Pr(\text{NLF}(x_4, x_3, x_2, x_1, x_0) = 1 \mid x_0 \oplus x_1 = 1) = 5/8$$

Best Determine-Slide Attack

- Data: 2^{32} known plaintexts (full codebook)
- Complexity: $\approx 2^{37}$ Keeloq encryptions

Slide/Fixed Point Attacks

Cycle Structure of Keeloq

Slide-Determine Attack

- Remove the $\frac{1}{4}$ cycle by guessing the first 16 key bits and decrypting the ciphertext by 16 rounds
- Given the pair (p, c) , Search for fixed points $f_k^8(p) = p$
 - About 2^{16} pairs will be found (birthday paradox)
- Store the triples $(p, c, (k_{15}, \dots, k_0))$
- Apply an algebraic attack to determine the unknown 48 key bits
- Verify solutions by checking additional plaintext-ciphertext pairs

Complexity

- Data: 2^{32} known plaintexts (full codebook)
- Version A: Average = $2^{31.1}$ Keeloq encryptions
- Version B (optimised): Average = $2^{27.7}$ Keeloq encryptions

Safe Keys

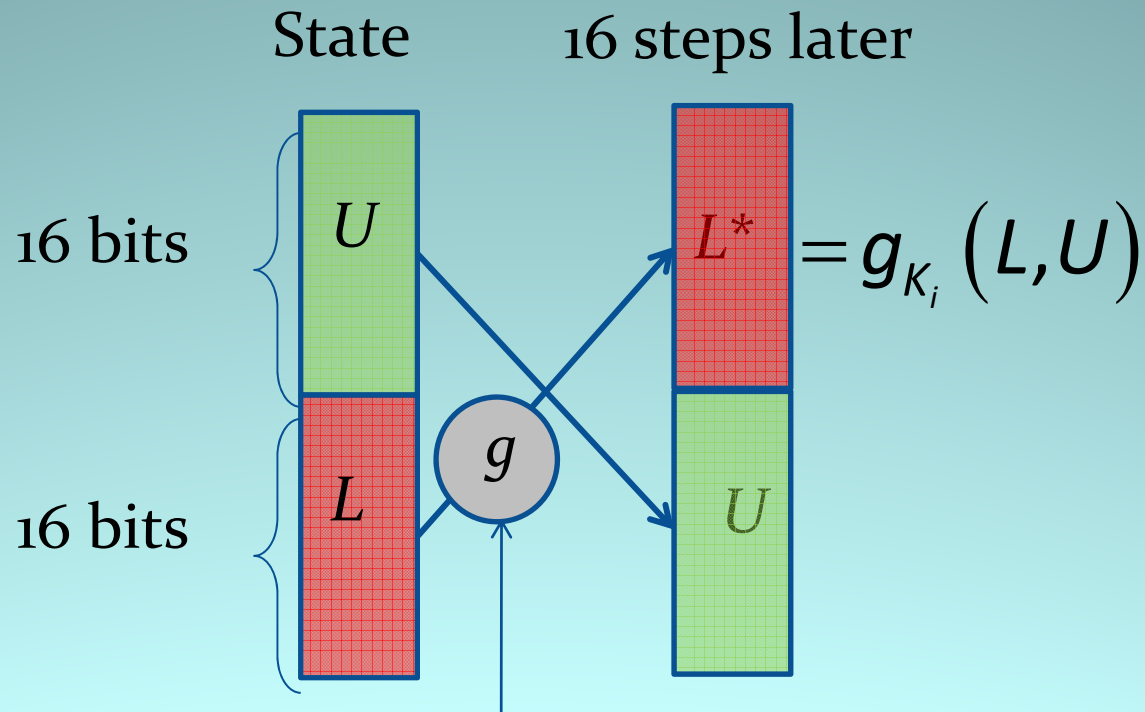

- The success of the attack depends on the existence of fixed points, and this is a function of the key
 - Version A works for about 63% of keys
 - The attack does not work for about 37% of keys
 - Optimised version A works for about 30% of keys

Slide/Meet-in-the-Middle Attack

Slide/Meet-in-the-Middle Attack

- Participating research groups
 - Computer science department, **Technion**, Israel
 - Research group COSIC of the **Katholieke Universiteit Leuven**, Belgium
 - Math department of the **Hebrew University**, Israel

Recovering Key Bits

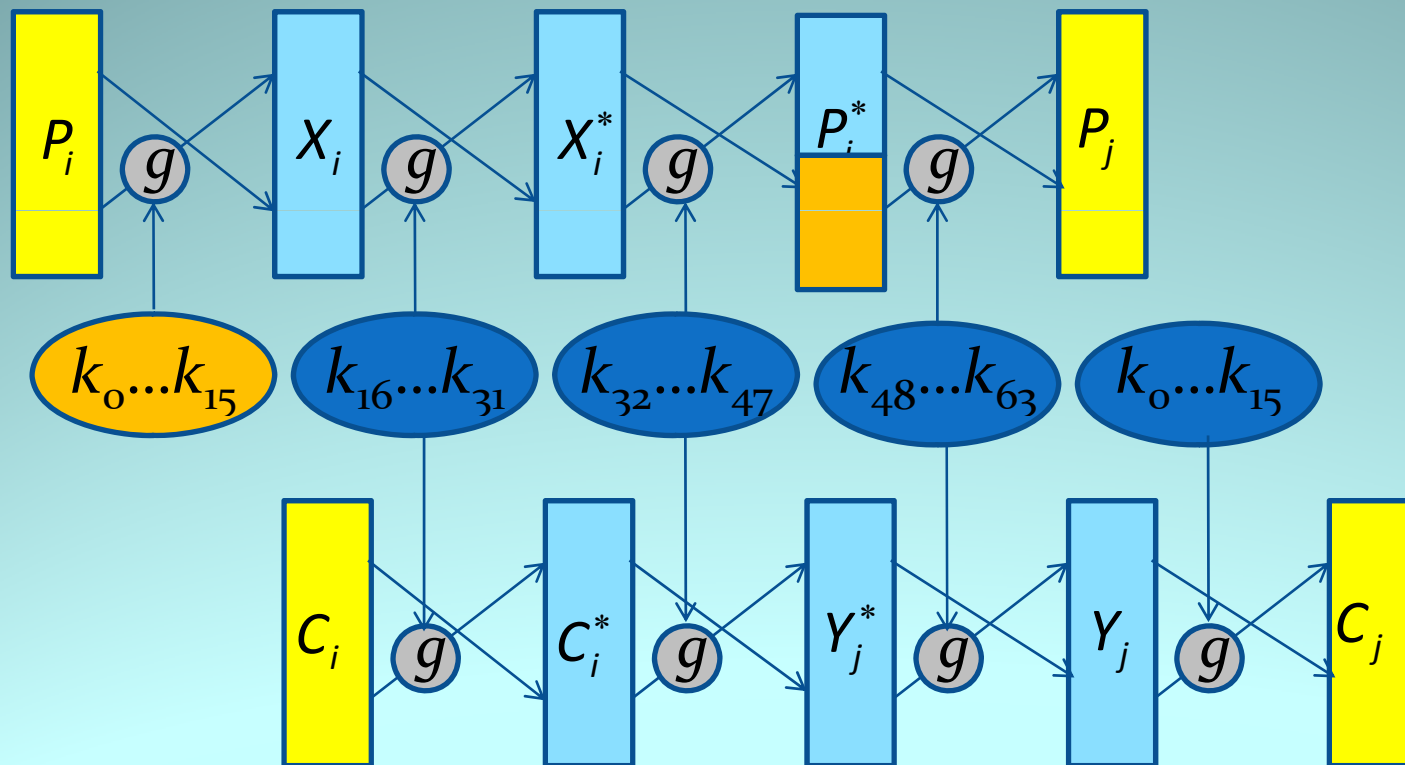

$$K_i = (k_{16i} \dots k_{16i+15}), \quad i = 0, 1, 2, 3$$

K_i is easily solved if L , L^* and U are known

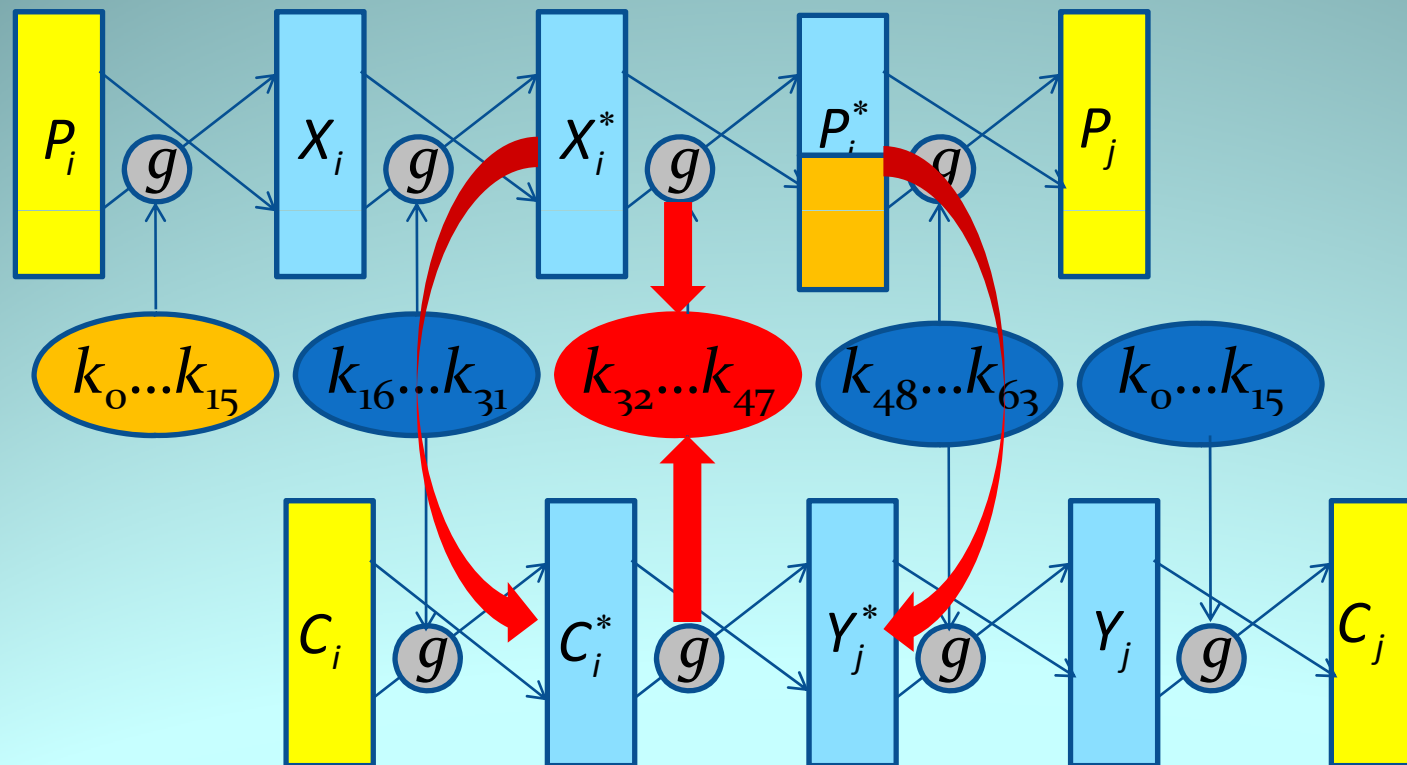

Meet-in-the-Middle Attack

Meet-in-the-Middle Attack

Meet-in-the-Middle Attack

Complexity of the Attack

$$2^{16}(32 \cdot 2^{16} + 2^{16}(32 \cdot 2^{16} + 2^{16}(32 + 4))) = 2^{54.0} \text{ rounds}$$

- Data: 2^{16} known plaintexts
 - 65 minutes to obtain data
- Time complexity: $2^{45.0}$ Keeloq encryptions
 - 7.8 days on 64 CPU cores
 - Variant requires 3.4 days on 64 CPU cores

Discussion

Discussion

- Keeloq has been successfully cracked, but a pure algebraic attack requires more research
- **Improvements:**
 - Scale up the Keeloq block and key lengths
 - Slight structural changes to the key schedule would stop slide attacks

Benefit of Hindsight

- The design team underestimated
 - The rapid progress in brute force computational capabilities
 - Discovery of new attacks, such as the slide attack

... should've attended EUROCRYPT.
